There are two large areas of research that are (as yet) banned from mainstream science: the subtle field area and the structured water one. It is worth noting that they are not necessarily separate. In our present study, using the Evapo method of water structure research introduced in the previous year at this conference, we examined the influences of the human biofield (long-range field) as well as short-range (subtle field) influences of two substances: nafion and glass on evapo mineral residues structures.

The Evapo method consists of creating drops of different solutions on clean microscope slides and drying them under defined conditions. Dry residues are then observed under the microscope. Properly dried drops with no additional artifacts are photographed and analyzed by visual assessment and / or specially created software.

In the present study we examined the impact of ordinary volunteers and 5 bioenergy healers on well-researched spring water. No contact with water was made, just an influence from a distance. Additionally, we also tested the impact of small and cleaned nafion beads as well as glass beads (contact experiments) on water structures.

The first series of experiments demonstrated that there was a considerable difference between the influence from ordinary people and healers, namely while the first group did not significantly change the structure of evapo water drops, the second did this even in a statistically significant manner. The short-range series of experiments demonstrated a remarkable influence of nafion on water structures (for instance a complete erasing of structures typical for this water even after only 5 minutes of exposure on one side and creating special patches of not yet identified residues even in distilled water drops on the other!). The influence of glass beads was only a little less astonishing – they remarkably and stably changed the structure of water and thereby its mineral residues structures.

The two series of experiments firmly support phenomena prohibited from the established science, namely the existence of a special field (biofield) emanating in its strong form from certain individuals (e.g. healers), the possibility of imprinting this field into water with a consequent possibility to detect such imprints, and the so-called water memory. Additionally, a strongly influencing short-range field from nafion and glass beads that can change the water structures even permanently or for a long time can be demonstrated. Further and more

extensive research will be needed for an estimation of various (biological, chemical, physical) consequences of these pilot research studies.
